

Environment Modules

'modules' command

It is a shell function used as the client to load and unload provided environments.

Using provided environments

What environments are available?

```
$ module avail
----- /etc/environment-modules/modules -----
-----
clang-llvm/7.0.1  cmake/3.8.0  gcc/6.5.0  rust/1.38.0
clang-llvm/9.0.0  gcc/4.9.4   gcc/7.4.0  swift/5.0.1
cmake/3.1.1      gcc/5.5.0   gcc/8.3.0
```

Loading an environment

```
$ module load clang-llvm/7.0.1

$ which clang
/usr/local/clang-llvm/7.0.1/bin/clang

$ clang --version
clang version 7.0.1 (tags/RELEASE_701/final)
Target: x86_64-unknown-linux-gnu
Thread model: posix
InstalledDir: /usr/local/clang-llvm/7.0.1/bin
```

Unloading an environment

```
$ module unload clang-llvm/7.0.1

$ which clang
/usr/bin/clang
```

/etc/profile.d/modules.sh

This is where the function gets imported into your environment. It should be sourced by default and you should not have to worry about this. However, if for some reason, you do not have the 'module'

function available to you, you might not be running a login shell or `/etc/profile.d/modules.sh` was not imported.

Known bugs

gnome-terminal

By default `gnome-terminal` does not start a login shell. There is a checkbox under `Edit > Preferences > <profile name> > Command > 'Run command as a login shell'`. Check that, and open a new terminal. The command should be available to you.

Assuming 'bash' as your shell but these directions should point any others in the right direction. You can also try `source /etc/profile.d/modules.sh` in your `$HOME/.bashrc`
