CLOUD CLI ACCESS

INSTALL

Pip is preferred. The general CS infrastructure is a good starting point. However, our experience has been that the software installs cleanly and is free from dependency problems.

Try:

python3 -m pip install --user python-openstackclient

CONFIGURATION

Use a clouds.yaml file to direct your client. Below is a canonical example, but you <u>will</u> have to modify the variables according to your account. <code>\$HOME/.config/clouds.yaml</code>

```
clouds:
    openstack:
        auth:
        auth_url: https://overcloud.cs.uchicago.edu:5000
        username: "CNetID"
        password: "sekret"
        project_name: "CNetID"
        user_domain_name: "CS_LDAP"
        region_name: "RegionOne"
        interface: "public"
        identity_api_version: 3
```

The Python Examples use the same configuration, please read that document for detailed information about configuration and recommendations.

You can also download a customized version of this data after you authenticate to the Web Interface (click API Access from the menu and then the button "Download Openstackrc File"). Make sure you read this file carefully in case you want to customize it. Your password is not included in the file by default.

USAGE

First, Take note of a loose UX pattern that the client has:

openstack \$resource \$action \$more_options_or_flags

take note and always use help for guidance

--help

For example

```
openstack server create --help
```

Once you have the software installed and the configuration file created, as above, you can start to use the client. What follows is an annotated example that will create an infrastructure of 10 Ubuntu hosts accessing the internet via a NAT device (SNAT), and with one of the hosts reachable at a separate public IP address (DNAT).

Annotated Example

Read what has been written above before you read this.

We use this command a lot

openstack server list

Images

Images are prebuilt disks that are used to launch instances. They are usually a few GB in size. A copy of the disk image is written into the instance's boot volume just before it starts running.

There are images that Techstaff provides, some of which are restricted-use. We can build images for you or you can build and upload your own. Our images are generic, bare bones, cloud enabled popular operating systems that are a firm foundation for you to customize from. They are often in RAW format, not qcow2, for performance reasons.

openstack image list

SSH Keys

Openstack can hold a public key in its db, and insert it into instances when told. This is optional (your author does not use this capability)

openstack keypair create --public-key ~/.ssh/id_rsa.pub mykey

Flavors

A flavor is a pre-chosen size for resources that make up an instance. It is a mandatory parameter when creating instances. Look at the available flavors, which your admins have created.

Servers can grow after creation. For example, the disk-size attribute merely expresses the

minimum size of the boot volume, and most cloud-enabled operating systems expand the root volume on first-boot. In spite of this, relying on dynamically resizing instances increases risk, and you should choose a size that is close to what you expect to use.

openstack flavor list

Networks

Look at the Networks that are available. The meaning of an Openstack "Network" captures L2 semantics, and houses L3 subnets. IPv6 is in preview mode at this time, and is not fully supported on the UC campus.

You are free to use the Network called <u>cloud</u>, if you don't need your hosts to be L2 isolated from other users, and you would like to proceed directly to creating servers.

Using the <u>cloud</u> network cuts down your complexity significantly, and can be changed later, or mixed with other modes at your leisure. Please talk with us if you want to attach a Router to the <u>cloud</u> network.

openstack network list

See also Advanced Networking hints.

Creating an Instance

You now have all of the prerequisites for launching a virtual computer. These are the prerequisites:

- Properly prepared Network or use the one called "cloud" if you don't care about the L2 boundary nor the source address of your NAT clients
- Flavor Name
- Image Name

NOTE: you won't be able to SSH into the instance, because the NAT is SNAT. Down below you can read how to add a dedicated public ("floating") IP address to any server.

Like other openstack activities, creating a server has <u>many</u> complex options and scenarios. This is a simple and ordinary depiction, creating one server

```
openstack server create \
    --image 20.04 \
    --boot-from-volume=32 \
    --flavor m1.medium \
    --config-drive=true \
    --user-data=/home/chudler/openstack/cluster_test/cloud-init.yml \
    --network cloud \
    myserver
```

The command executed asynchronously, check the status, or supply the -wait option next time:

```
Last update: 2020/05/14 10:39
```

cloud:cli

```
openstack server list --name myserver
```

```
openstack server show myserver
```

Here's an example for creating 10 of them, as promised (only the change at the end of the command)

```
openstack server create \
    --image 20.04 \
    --boot-from-volume=32 \
    --flavor m1.medium \
    --config-drive=true \
    --user-data=/home/chudler/openstack/cluster_test/cloud-init.yml \
    --network cloud \
    --min 10 \
    --max 10 \
    myserver
```

Mandatory Firewall Rules

If you are using the default security groups, all ingress network communication is dropped.

Here's a nasty thing I use to determine what the security group is for a server (it can be determined also by looking at security groups directly) [ITS BRITTLE, BEWARE]

```
SEC_GROUP=$(openstack port list \
    --server `openstack server show --format value --column id myserver` \
    --long \
    --column "Security Groups" \
    --format json \
    | jq '.[]."Security Groups"[]' \
    | sed 's/"//g')
```

If I learned the security group successfully, I can let in SSH.

```
openstack security group rule create \
    --ingress \
    --dst-port 22 \
    --protocol tcp $SEC_GROUP
```

In actual fact, all of the servers you create will be in the same security group.

Internet Addresses

If the server's status shows "Active", you can assign it an additional IP address. When doing networking work, you might wish to connect to web interface to access the console of the virtual machine.

As in Advanced Networking get a campus IP address from our pool.

5/6

Where do you want to create your floating IP?

openstack network list

Use the network from the previous command:

openstack floating ip create campus37

You now have an IP you can use:

openstack server add floating ip myserver <floating_ip_address>

At last, you can ssh into 128.135.37.XX. It is important for you to realize that your <u>local</u> server IP does not change (no new interface is given to the instance). Instead, the router on the subnet simply performs DNAT on behalf of the clients.

Here's another possibility:

\$ openstack server add network myserver campus37

Now your server does have a **new** network interface attached to it, and will be served a DHCP address on it. You will almost certainly have to inform the OS about this manually; the cloud may not help you do that.

This section added a floating ip address directly to the server. You must realize that a router was needed on the subnet for that to happen. On default subnets, your cloud admin has pre-created suitable routers. The command will fail if you are creating your own subnets and networks without taking similar steps.

A WORD ABOUT CLOUD INIT

Your author uses cloud init extensively and does not contemplate alternative. It is optional. A minimal cloud-init for a modern Ubuntu cloud OS might look like this

```
OpenStack:
  metadata_urls: ["http://169.254.169.254"]
  max_wait: -1
  timeout: 10
  retries: 5
  apply_network_config: true
manage_etc_hosts: false
manual_cache_clean: false
```
